## Chapter 2: Motion in one dimension

## 2-1- Position

A particle's position x is the location of the particle with respect to a chosen reference point that we can consider to be the origin of a coordinate system.

## 2-2- Displacement and Distance

The displacement $\Delta \mathrm{x}$ of a particle is defined as its change in position. As it moves from an initial position $x_{i}$ to a final position $x_{f}$, we write the displacement of the particle as
$\Delta \mathrm{x}=\mathrm{x}_{\mathrm{f}}-\mathrm{x}_{\mathrm{i}}$
From this definition we see that $\Delta x$ is positive if $x_{f}$ is greater than $x_{i}$ and negative if $x_{f}$ is less than $\mathrm{x}_{\mathrm{i}}$.

Displacement is an example of a vector quantity. We use plus and minus signs to indicate vector direction. Any object always moving to the right undergoes a positive displacement $+\Delta x$, and any object moving to the left undergoes a negative displacement $-\Delta x$.

It is very important to recognize the difference between displacement and distance traveled.
Distance $\mathbf{d}$ is the length of a path followed by a particle.

Ex: What is the difference between distance and displacement?

| Displacement | Distance |
| :---: | :---: |
| Vector quantity (has direction and magnitude) | Scalar quantity (has magnitude only) |
| Positive or negative | Always positive |
| It's magnitude is shortest length between two |  |
| points |  | | is the length between two points longer than |
| :---: |
| straight line between them |

## 2-3- Average velocity and speed

The average velocity $\bar{v}_{x}$ of a particle is defined as the particle's displacement $\Delta x$ divided by the time interval $\Delta t$ during which that displacement occurred:
$\overline{\mathrm{v}}_{\mathrm{x}}=\frac{\Delta \mathrm{x}}{\Delta \mathrm{t}}$
where the subscript " $x$ " indicates motion along the $x$-axis. The average velocity has dimensions of length divided by time (L/T), or meters per second in SI units.

There is a clear distinction between speed and velocity. The average speed $\bar{v}$ of a particle, a scalar quantity, is defined as the total distance traveled d divided by the total time it takes to travel that distance:

$$
\overline{\mathrm{v}}=\frac{\mathrm{d}}{\Delta \mathrm{t}}
$$

The SI unit of average speed is the same as the unit of average velocity: meters per second. However, unlike average velocity, average speed has no direction and hence carries no algebraic sign.

Ex: Find the displacement, average velocity, and average speed of the car in the following figure between positions $A$ and $F$. Note that $X_{A}=30 \mathrm{~m}$ at $\mathrm{t}=0 \mathrm{sec}$ and that $X_{F}=-53 \mathrm{~m}$ at $\mathrm{t}=50 \mathrm{sec}$

| Position | $\mathrm{t}(\mathrm{s})$ | $\mathrm{x}(\mathrm{m})$ |
| :---: | :---: | :---: |
| A | 0 | 30 |
| B | 10 | 52 |
| C | 20 | 38 |
| D | 30 | 0 |
| E | 40 | -37 |
| F | 50 | -53 |

## Soln:

$$
\begin{aligned}
& \Delta \mathrm{x}=\mathrm{x}_{\mathrm{F}}-\mathrm{x}_{\mathrm{A}}=-53 \mathrm{~m}-30 \mathrm{~m}=-83 \mathrm{~m} \\
& \overline{\mathrm{v}}_{\mathrm{x}}=\frac{\Delta \mathrm{x}}{\Delta \mathrm{t}}=\frac{-53-30}{50-0}=-1.7 \mathrm{~m} / \mathrm{s} \\
& \overline{\mathrm{v}}=\frac{\mathrm{d}}{\Delta \mathrm{t}}=\frac{127}{50}=2.5 \mathrm{~m} / \mathrm{s}
\end{aligned}
$$

## 2-4- Instantaneous velocity and speed

Instantaneous velocity $v_{x}$ equals the limiting value of the ratio $\Delta x / \Delta t$ as $\Delta t$ approaches zero

$$
\mathrm{v}_{\mathrm{x}}=\lim _{\Delta \mathrm{t} \rightarrow 0} \frac{\Delta \mathrm{x}}{\Delta \mathrm{t}}=\frac{\mathrm{dx}}{\mathrm{dt}}
$$

The instantaneous velocity can be positive, negative, or zero. In the following figure, when the slope of the position-time graph is positive, such as at any time during the first $10 \mathrm{~s}, \mathrm{v}_{\mathrm{x}}$ is positive. After point $B, v_{x}$ is negative because the slope is negative. At the peak, the slope and the instantaneous velocity are zero.

The instantaneous speed of a particle is defined as the magnitude of its velocity.

Ex: A particle moves along the $x$-axis. Its $x$ coordinate varies with time according to the expression $x=-4 t+2 t^{2}$ where $x$ is in meters and $t$ is in seconds. The position-time graph for this motion is shown in following figure. Note that the particle moves in the negative $x$ direction for the first second of motion, is at rest at the moment $t=1 \mathrm{~s}$, and moves in the positive $x$ direction for $t>1 \mathrm{~s}$.
a) Determine the displacement of the particle in the time intervals $t=0$ to $t=1 \mathrm{sec}$ and $t=1 \mathrm{~s}$ to $t=3 \mathrm{~s}$.
b) Calculate the average velocity during these two time intervals.
c) Find the instantaneous velocity of the particle at $t=2.5 \mathrm{~s}$.

## Soln:

a)

$$
\begin{aligned}
& \Delta x_{(A) \rightarrow(B)}=x_{f}-x_{i}=x_{(B)}-x_{(A)} \\
& =\left[-4(1)+2(1)^{2}\right]-\left[-4(0)+2(0)^{2}\right]=-2 \mathrm{~m} \\
& \Delta x_{(B) \rightarrow(®)}=x_{f}-x_{i}=x_{(®)}-x_{(B)} \\
& =\left[-4(3)+2(3)^{2}\right]-\left[-4(1)+2(1)^{2}\right]=+8 \mathrm{~m}
\end{aligned}
$$

b)

$$
\begin{aligned}
& \overline{\mathrm{V}}_{\mathrm{x}_{(® \rightarrow(B)}}=\frac{\Delta x_{\circledR \rightarrow(®)}}{\Delta t}=\frac{-2 \mathrm{~m}}{1 \mathrm{~s}}=-2 \mathrm{~m} / \mathrm{s} \\
& \overline{\mathrm{~V}}_{\mathrm{x}(® \rightarrow(®))}=\frac{\Delta x_{(® \rightarrow(®)}}{\Delta t}=\frac{8 \mathrm{~m}}{2 \mathrm{~s}}=+4 \mathrm{~m} / \mathrm{s}
\end{aligned}
$$

c)
$\mathrm{v}_{\mathrm{x}}=\frac{\mathrm{dx}}{\mathrm{dt}}=-4+4 \mathrm{t}$
$\mathrm{v}_{\mathrm{x}}(\mathrm{t}=2.5)=6 \mathrm{~m} / \mathrm{s}$

## 2-5- Acceleration

The average acceleration $\bar{a}_{x}$ of the particle is defined as the change in velocity $\Delta v_{x}$ divided by the time interval $\Delta t$ during which that change occurred:

$$
\bar{a}_{x}=\frac{\Delta v_{x}}{\Delta t}=\frac{v_{x_{f}}-v_{x_{i}}}{t_{f}-t_{i}}
$$

As with velocity, we can use positive and negative signs to indicate the direction of the acceleration. Acceleration has dimensions of length divided by time squared, or $\mathrm{L} / \mathrm{T}^{2}$. The SI unit of acceleration is meters per second squared $\left(\mathrm{m} / \mathrm{sec}^{2}\right)$.

The instantaneous acceleration equals the derivative of the velocity with respect to time

$$
\mathrm{a}_{\mathrm{x}}=\lim _{\Delta \mathrm{t} \rightarrow 0} \frac{\Delta \mathrm{v}_{\mathrm{x}}}{\Delta \mathrm{t}}=\frac{\mathrm{dv}_{\mathrm{x}}}{\mathrm{dt}}
$$

If $a_{x}$ is positive, then the acceleration is in the positive $x$ direction; if $a_{x}$ is negative, then the acceleration is in the negative $x$ direction. The acceleration can also be written

$$
\mathrm{a}_{\mathrm{x}}=\frac{\mathrm{dv}_{\mathrm{x}}}{\mathrm{dt}}=\frac{\mathrm{d}}{\mathrm{dt}}\left(\frac{\mathrm{dx}}{\mathrm{dt}}\right)=\frac{\mathrm{d}^{2} \mathrm{x}}{\mathrm{dt}^{2}}
$$

Ex: The velocity of a particle moving along the $x$-axis varies in time according to the expression $v_{x}=\left(40-5 t^{2}\right) \mathrm{m} / \mathrm{s}$, where t is in seconds. (a) Find the average acceleration in the time interval $\mathrm{t}=0$ to $\mathrm{t}=2.0 \mathrm{~s}$. (b) Determine the acceleration at $\mathrm{t}=2.0 \mathrm{~s}$.

## Soln:

a)
$\bar{a}_{x}=\frac{v_{x f}-v_{x i}}{t_{f}-t_{i}}$
$v_{x A}=40-5(0)^{2}=40 \mathrm{~m} / \mathrm{s}$
$v_{x B}=40-5(2)^{2}=20 \mathrm{~m} / \mathrm{s}$
$\bar{a}_{x}=\frac{\mathrm{v}_{\mathrm{xB}}-\mathrm{v}_{\mathrm{xA}}}{\mathrm{t}_{\mathrm{B}}-\mathrm{t}_{\mathrm{A}}}=\frac{(20-40) \mathrm{m} / \mathrm{s}}{(2-0) \mathrm{s}}=-10 \mathrm{~m} / \mathrm{s}^{2}$
b)
$\mathrm{a}_{\mathrm{x}}=\frac{\mathrm{dv}_{\mathrm{x}}}{\mathrm{dt}}=-10 \mathrm{tm} / \mathrm{s}^{2}$
$\mathrm{a}_{\mathrm{x}}(\mathrm{t}=2 \mathrm{~s})=-20 \mathrm{~m} / \mathrm{s}^{2}$
